International Center for Agricultural Research in the Dry Areas

Established in 1977, the International Center for Agricultural Research in the Dry Areas (ICARDA) is governed by an independent Board of Trustees. Based at Aleppo, Syria, it is one of 16 centers supported by the Consultative Group on International Agricultural Research (CGIAR), which is a consortium of over 40 countries, international and regional organizations, and private foundations.

The CGIAR seeks to enhance and sustain food production and, at the same time, improve socioeconomic conditions of people, through strengthening national research systems in developing countries.

ICARDA focuses its research efforts on areas with a dry summer and where precipitation in winter ranges from 200 to 600 mm. The Center has a world responsibility for the improvement of barley, lentil, and faba bean, and a regional responsibility--in West Asia and North Africa--for the improvement of wheat, chickpea, and pasture and forage crops and the associated farming systems.

Much of ICARDA's research is carried out on a 948-hectare farm at its headquarters at Tel Hadya, about 35 km southwest of Aleppo. ICARDA also manages other sites where it tests material under a variety of agroecological conditions in Syria and Lebanon. However, the full scope of ICARDA's activities can be appreciated only when account is taken of the cooperative research carried out with many countries in West Asia and North Africa.

The results of research are transferred through ICARDA's cooperation with national and regional research institutions, with universities and ministries of agriculture, and through the technical assistance and training that the Center provides. A range of training programs are offered extending from residential courses for groups to advanced research opportunities for individuals. These efforts are supported by seminars, publications, and by specialized information services.

The Weather in Northern Syria During the 1989/90 Season

The season of 1989/90 in Northern Syria was in many ways similar to the 1988/89 season. Overall rainfall was almost exactly the same, reaching about two thirds of the long-term average. The total number of frost days was also similar and, with around 50, markedly above the average. Even the intraseasonal distribution of rainfall and frost was reminiscent of the previous year. In both years, most of the rain fell early on in the season, and January was by far the coldest month with most frost days, followed by February. Yet there were significant differences: rainfall in 1989/90 did not stop quite as abruptly as the year before, there was significant precipitation during February; and there was a very severe frost period in March 1990.

The season started with ample rain falling in distinct spells from 12 November to 11 December. This made timely planting easy and ensured a good early crop development. However, the rest of December and January were rather dry except for one wet spell around the turn of the year, and January temperatures were noticeably cooler than average (there was frequent frost down to -8°C), so that by end of January crop stands were visibly poorer than the year before at the same time. The February rainfall total was average, nearly all of it falling before 18 February. No significant rainfall was recorded after that except for one shower at the start of April. With the dry weather in the second half of February and in March, night temperatures dropped again and stayed well below average until well into April. Late frosts in March (-8.9°C in Tel Hadya on 17 March) inflicted severe damage, especially in the drier part of the area, although they were less severe in the wetter part. Soil moisture reserves for the later growth stages of the crops were better than in the season before, due to the later cessation of rainfall and smaller losses to evaporation. Those crops, which had not been too much afflicted by frost, in the wetter parts of the area were therefore still able to produce fair yields, whereas many crops in the drier parts were unable to compete successfully for the remaining moisture with soil surface evaporation during the terminal drought and yielded little or nothing. Grazing of crops was again widespread in these drier areas and, on the whole, the season of 1989/90 was as disastrous as the one of 1988/89.

TEL HADYA
(SYRIA)

1989-1990 Season

Latitude	Longitude	Elevation
36°01'N	36°56'E	284 m

NOTE:

- 1- In addition to the standard class A pan ("Evap. Pan A"), evaporation is measured with two other pans of the same dimensions at Tel Hadya. These are covered with a loose mesh to prevent interference from birds and other animals. One of the so protected pans is raised above the ground like the original class A pan ("Evap. Pan A (Mesh)"). Observations from this pan were reported as pan evaporation in previous reports in this series up to 1987/88. The second mesh-protected pan is sunk into the ground so that the water surface is level with the ground surface ("Evap. A-size Sunk-M"). Further evaporation measurements are taken at Tel Hadya with a GGI-3000 pan, Wild evaporation scales and a Piche evaporimeter. All these instruments are located at the main meteorological station ("1" on the plan on page 57). The evaporation pans at all other sites are standard class A pans.
- 2- Precipitation at Tel Hadya is measured at a number of points in addition to the main meteorological station. The positions of these precipitation stations and that of the main meteorological station are shown on the plan on page 57. At the main meteorological station and on the hilltop, precipitation is measured with a standard raingauge at one meter above the ground. At the main station, precipitation is also measured with a GGI-3000 raingauge at ground level. The instruments at the other locations are plastic raingauges (102 mm diameter) at one meter above the ground.
