Agroecological approach to agricultural intensification

Boris Boincean dr. habilitate, research professor Selectia Research Institute of Field Crops Alecu Russo Balti State University Balti, Republic of Moldova

> International Symposium – Sharing Knowledge across North Africa, Central Asia and Europe

> > November 14-15, 2019 Rabat, Morocco

Agriculture in all over the world, including in the Republic of Moldova, is facing many challenges at the moment and, especially, for the future:

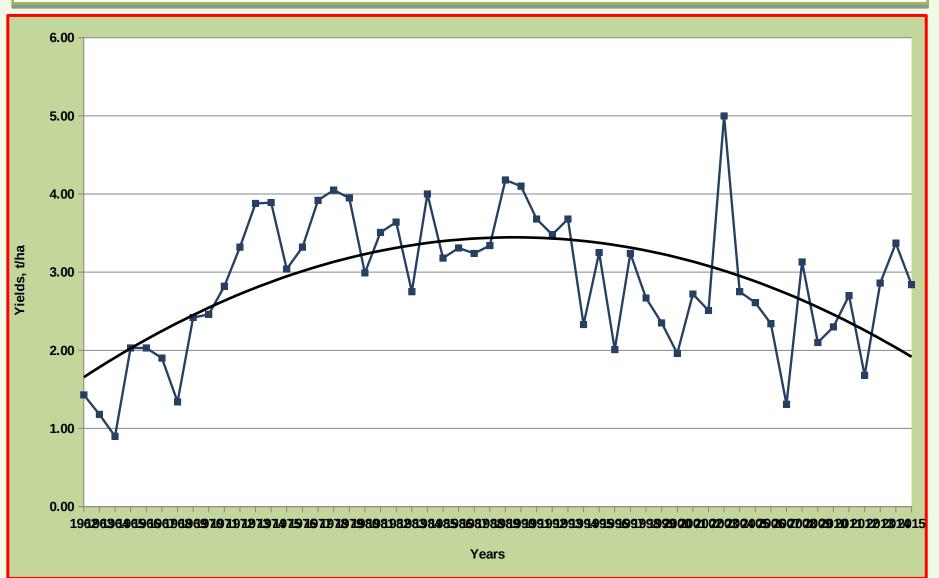

- Limited natural resources, including nonrenewable sources of energy (oil, natural gasses, coal) with regularly increased prices on them
- Worsening of economic conditions for farmers activities because of unfair increased prices for industrial inputs and agricultural products
- Providing food security at the local, regional and global levels in the conditions of higher density of population and climate changes
- Biodiversity losses including genetic losses both on the surface of the soil and, especially, in the soil
- Soil degradation and danger of ground waters and food pollution on the whole food chain in the conditions of the globalization of economy
- Increased negative consequences of the global warming with more frequent manifestation of droughts (heats) and other natural calamities
- Rural community disintegration
- Increased expenses for public health (nontransmisible diseases)

|                | NPK 175                                     | 0.33  | 0.75   |

- Industrial model of agricultural intensification based on the concept of "Green Revolution" didn't address many of the above mentioned challenges and consequently didn't provide a sustainable development. It means agriculture is in crisis
- Agriculture is mainly directed towards higher level of yields and profit in the condition of market economy
- "Agriculture as usual doesn't work"
- Soil is a living organism and it plays a poly-functional role by providing ecosystem and social services
- Agriculture in all over the world requires change of the paradigm of the agricultural intensification – transition from industrial inputs to a better recycling of energy and nutrients in each farm predominantly by using renewable sources of energy of local origin

#### Tab.2 "Effect of crop rotation" in the long-term field experiments of Selectia RIFC (Balti, Republic of Moldova), average for 15 years, t/ha and %

- The higher is the diversity of crops in the crop rotation the higher is the functionality of soil as a result of a higher biodiversity of organisms for the whole soil food chain
- The better are the predecessors for winter wheat the lower are the extra yields from fertilization. Yields reduction from sowing winter wheat after late harvested predecessors is significantly higher than extra yields from fertilization
- The share of soil fertility in yield formation of winter wheat is significantly higher after early harvested predecessors than after latter harvested predecessors or permanent cropping
- Nitrogen use efficiency from mineral fertilizers is the lowest when applied after early harvested predecessors and it increases after late harvested predecessors

Tab. 6 Yields of winter wheat under the influence of different systems of soil tillage and fertilization in crop rotations with and without mixture of legumes and grasses, average for 3 rotations in the poly-factorial experiment at RIFC, Balti, Moldova, t/ha and %

- By including perennial leguminous crops (alfalfa) in the crop rotation soil quality and yields of winter wheat and corn for grain are increasing, especially in drought conditions, relatively to crop rotations without perennial legumes and permanent monocropping
- Accumulation of soil moisture under corn for grain during fallspring period of time is higher in crop rotation with perennial legumes (alfalfa), especially in drought conditions
- Carbon sequestration is higher in deeper soil layers for crop rotations with lucerne
- Black fallow is less efficient in accumulation of soil moisture relatively to monoculture of corn for grain and especially, with crop rotation
- In crop rotations with the mixture of legumes and grasses the yields of winter wheat and corn for grain are similar irrespective of applied system of fertilization and soil tillage

- On soils with good quality (health) mechanical tillage can be replaced by biological tillage
- Agroecological approach to agricultural intensification supposes a holistic (systemic) approach to agricultural intensification in order to conserve local resources by managing relatively small-scale agriculture
- A new regenerative farming system allows to make agriculture truly sustainable by increasing the economic competitiveness through reducing reliance on agrochemicals and fuel and by reducing the negative environment and social impact of farming systems, including higher resilience to global warming

#### Tab. 11 Structural and functional differences between natural ecosystems and agroecosystems (Odum, 1969 and Gliessman, 2000)

| Indicators   | Natural ecosystems | Agroecosystems |
|--|--------------------|----------------|
| Net productivity                                     | Medium             | High           |
| Trophic interaction                                  | Complex            | Simple, linear |
| Species diversity                                    | High               | Low            |
| Genetic diversity                                    | High               | Low            |
| Nutrient and energy cycles                           | Closed             | Open           |
| Stability (resilience)                               | High               | Low            |
| Human control  | Independent        | Dependent      |
| Temporal performance                                 | Long               | Short          |
| Habitat heterogeneity<br>(ecological infrastructure) | Complex            | Simple         |

#### Soil quality (soil health) is crucial in the transition to a more sustainable agriculture

- Soil organic matter (humus) is an integral index of soil fertility (soil quality, soil health)
- Changes in the soil structure due to compaction by heavy farm equipment suppress root development, thus reducing the quantity of soil nutrients and water that can be accessed by crops
- A decline in soil organic matter following intensive tillage can reduce the water-holding capacity of a soil, making the crop more susceptible to water deficits and drought during the growing season
- A soil with good physical, chemical and biological, proprieties is able to produce higher crop yields, can generate more income than a poor – quality soil

## Physical, chemical and biological soil indicators for assessing soil quality (John Doran, 1996):

- A. Physical:
  - \* Texture
  - \* Top soil depth
  - Water infiltration rate
  - Bulk density
  - Water holding capacity
- B. Chemical:
  - \* Soil organic matter
  - ✤ Total nitrogen
  - \* рН
  - Electrical conductivity
  - \* Extractable nutrients (N, P, K)
- C. Biological
  - Microbial biomass carbon
  - Microbial biomass nitrogen
  - Potentially mineralizable nitrogen
  - \* Soil respiration Earthworms

A good quality soil can provide besides a relevant crop production, a better ecosystem services:

- filtering and purifying water before it is released to waterways
- inorganic and organic pollutants can be absorbed and some can be degraded
- buffer for climate changes by promoting the growth of plants that sequester CO<sub>2</sub> from the atmosphere and contributing to the humification and physical protection of carbon from plants and other organic residues
- healthy soil provides health for the whole chain: crops animals – people
- changing the habits to eat will stimulate transition to a more sustainable agriculture.

Tab. 12 The effect of crop rotation and fertilization for winter barley sown by using No-till after corn for grain, average for 2015-2018 years, long-term field experiment at Selectia Research Institute of Field Crops, Balti, Republic of Moldova

| Crop rotation |         | Permanent cropping |         | Extra yields from crop<br>rotation |             | Extra yields from<br>fertilization |                          |
|---------------|---------|--------------------|---------|------------------------------------|-------------|------------------------------------|--------------------------|
| unfert.       | fertil. | unfert.            | fertil. | unfert.                            | fertil.     | in crop<br>rotation                | in permanent<br>cropping |
| 2.39          | 5.19    | 1.56               | 4.03    | +083/53.2%                         | +1.16/28.8% | +2.8/117.2%                        | +2.47/158.3%             |

- 1. Winter barley is less receptive to crop rotation than winter wheat, but more influenced by the fertilization system
- 2. Application of composted farmyard manure together with mineral fertilizers in crop rotation doesn't allow to distinguish their separate action

Tab. 13 Yields of No-till winter barley (sown after corn for grain) in crop rotation with and without mixture of alfalfa and reigras for green mass on different systems of fertilization, average for 2015-2018, t/ha

| Fertilization<br>systems in crop | -    | he mixture of alfalfa<br>or green mass | Crop rotation without mixture of alfalfa<br>and reigras for green mass |            |  |
|----------------------------------|------|--|--|------------|--|
| rotation                         | t/ha | ± and %                                | t/ha   | ± and %    |  |
| Without<br>fertilization         | 2.49 | -                                      | 2.72   | -          |  |
| Farmyard manure                  | 4.44 | +1.95/78.3                             | 4.71   | +1.99/73.2 |  |
| Farmyard manure<br>+ PK          | 4.67 | +2.18/87.6                             | 4.72   | +2.00/73.5 |  |
| Farmyard manure<br>+ NPK         | 4.62 | +2.13/85.5                             | 4.86   | +2.14/78.7 |  |

- Application of composted farmyard manure in crop rotation with and without mixture of perennial legumes and grasses is increasing significantly the yields of No-till winter barley (1.95 t/ha up to 2.18 t/ha or on 78.3% up to 87.6%)
- Supplementary application of mineral fertilizers to composted farmyard manure didn't increase significantly yields of No-till winter barley
- Application of composted farmyard manure in the crop rotation with the mixture of perennial legumes and grasses allows to improve soil fertility and maintain high level of yields without supplementary application of mineral fertilizers

Tab. 14 Yields and soil moisture accumulation during the fall-winter-spring periods of time for No-till winter barley sown after peas for grain (crop rotation N 2) and corn for grain (crop rotations N4 and N5), t/ha, average for 2015-2018 years, Selectia RIFC, Balti, Republic of Moldova

| Crop rotations    | Predecessors   | Yields, t/ha<br>(average for<br>2015-2018) | Yields, t/ha<br>(average for<br>2015-2016) | Soil moisture accumulation<br>during fall-winter-spring periods<br>of time, average for 2015-2016,<br>mm |          |  |

|                   |                |  |  |  |          |  |

DL =

0.19

0.17

- Yields No-till winter barley after peas for grain is equal to yields obtained after corn for grain, thanks to a higher accumulation of soil moisture during fall-winter-spring periods of time after harvesting corn for grain relatively to peas for grain
- Accumulation of soil moisture is higher in deeper soil layer for Notill winter barley sown after corn for grain in crop rotation with perennial legumes, which is increasing resilience to drought

### Conclusions

- 1. Conservation agricultural system requires a holistic approach to farm management through respecting crop rotation with higher diversity of main and successive (cover) crops including mixture of perennial legumes and grasses
- 2. Integration of crop and animal husbandries allows to improve soil, fertility thus reducing the application of industrial inputs (mineral fertilizers, pesticides)
- 3. No-till in crop rotation with perennial legumes and grasses is able to improve the quality of predecessors and to increase resilience to drought thanks a higher capacity to accumulate soil moisture during fall-winter-spring periods of time, especially in deeper soil layers

Thank you for your attention!
