Global - Poverty

Global drylands and agriculture resource poverty

Agricultural resource poverty is a structural component of environmental poverty, which is principally determined by climatic, topographic and soil constraints, as well as lack of water resources for irrigation, where needed. This global map shows a quantified estimate of the constraints to agriculture as imposed by the biophysical environment, using an index approach, scaled to a range 0-100, with 100 expressing the highest degree of resource poverty. The map has been compiled as a synthesis of individual thematic resource poverty maps (climate, topography, soils and irrigation water resources).

Download

Global drylands and soil resource poverty

The Soil Resource Poverty Index is the percentage of each grid cell occupied by problem soils. Problem soils include the following categories: saline soils, soils with high sodium content, shallow soils, sandy soils, soils with very poor profile development, soils with severe soil structural and/or textural limitations, soils with severe acidity, infertility or Al-toxicity problems, wetland soils, acid sulphate soils.

Download

Global drylands and topographic resource poverty

Landscapes that are strongly dissected, i.e. with high elevation differences, contain little land with agricultural value. Where such land exists, it is mostly located in narrow, often disconnected and poorly accessible valleys. On the other hand, flat landforms (plains and plateaux) in general have little land with unsuitable topography. Of course, even in flat areas unsuitable soils or even rock outcrops may occur, but these can be identified from the soil maps and will result in a high Soil Resource Poverty Index. Given the strict separation between topographic and soil resources, the methodology does not allow double counting.

The Topographic Resource Poverty Index (TRPI) is the percentage of each grid cell with slopes above 15%.

For areas between 60° N and 60° S, TRPI is obtained from the SRTM DEM by first identifying those areas with slopes > 15%, followed by aggregation of the result raster to a cell size of SRTM30 DEM (0.008333 decimal degrees), using summation as aggregation technique.

For areas above 60° N, SRTM data are not available and the TRPI was calculated by a relationship established between the TRPI and a low-resolution proxy indicator of slope, obtained from a 1-km DEM. The proxy indicator is the range, or the maximum elevation difference between neighbouring pixels, obtained from the global SRTM30 DEM. The range was for these areas converted into estimated values of TRPI by regression

Absolute change in annual trend precipitation 1901-2007

This map is based on the Full Data Reanalysis Product Version 4 of the Global Precipitation Climatology Centre (GPCC). It has been obtained by linear regression fitted to the 107-year time series of annual precipitation of each 0.5x0.5 degree grid cell by the least-squares method and subsequent resampling to 0.008333 degree (about 1 km) spatial resolution. The map shows the average absolute change in mm/year as measured along the trend line between 1901 and 2007. With some exceptions (e.g. parts of the Black Sea coast and the rim of Central Asia mountains) the trend is negative in most of the region.

Accessibility to markets

This map shows travel time to cities with at least 50,000 inhabitants as an indicator of accessibility to markets.

Agricultural Resource Capital and Population Density

A high-potential agricultural resource base can be insufficient for a large rural population, whereas areas with lower potential for agriculture but also lower population densities can be sustainable. This map links agricultural resource poverty to population density.

Benchmark areas, action and satellite sites of the West Asia-North Africa target region

The map shows a Benchmark Area in West Asia representing SRT2-conditions, and one in North Africa typical for SRT3-conditions. The West Asia Benchmark Area contains two Action Sites. SRT2-AS1 contains the area where research is conducted on the Rangeland-livestock based system in Jordan and Syria. SRT2-AS2 contains the area where research is conducted on the low-potential rainfed mixed crop-livestock based system. The North Africa Benchmark Area contains one Action Site (SRT3-AS1 in Morocco) where research is conducted on sustainable intensification of

Suitability for Water Harvesting : Macro - Catchment system Areas Suitable for agricultural use

The modeling of suitability for macro-catchments is more complicated than for micro-catchments, because the run-off is generated outside the pixel to be evaluated, and is a largely unknown quantity. The evaluation of suitability for macro-catchments requires the separate evaluation of suitability for a 'catchment' area and for a 'use' area. The criteria for the 'catchment' and 'use' areas are different: - for the catchment area, strongly sloping land with soils that are shallow, rocky, or have poor infiltration capacity is preferable; - for the use area, level or gently undulating land with deep soils and no other limitations to agricultural use is preferable -.

Suitability for Water Harvesting : Micro - Catchment system Contour bench terraces

The systems evaluated include 13 micro-catchment systems, based on combinations of 6 techniques and 3 crop groups, and one generalized macro-catchment system. The environmental criteria for suitability were based on expert guidelines for selecting water-harvesting techniques in the drier environments. They included precipitation, slope, soil depth, texture, and salinity, as well as land use/land cover and geological substratum. The dataset included interpolated surfaces of mean annual precipitation, a high-resolution digital elevation model, a soil map of Syria, a land use/land cover map of Syria, and a geological map of Syria. Contour-bench terraces are constructed on very st...

Integrated Water and Land Management Program

To assist the targeting of water saving technologies, the GISU is developing, in association with the IWLM, methodologies for assessing the biophysical potential for water harvesting and supplemental irrigation. Map products are currently available for Syria (Fig. 1) but outscaling to the level of all dryland areas is planned in the case of micro-catchment water harvesting techniques.

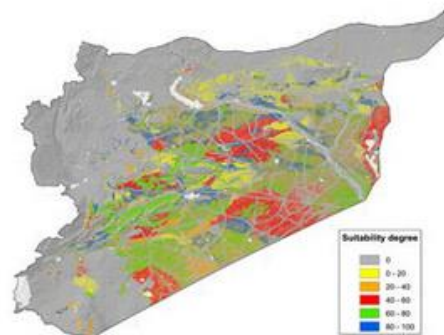

Fig.1. Suitability for water harvesting in Syria, micro-catchment systems, small-runoff basins, tree crops

In collaboration with the Plant Stress and Water Conservation Laboratory of the USDA Agricultural Research System in Lubbock, Texas, a geospatial tool, the ICARDA Agroclimate Tool, was developed, which predicts the risk of climatic stress (drought, heat, cold) for specific environments in CWANA (Fig.2).

The ICARDA Agro-Climate Tool

The ICARDA Agro-Climate Tool (hereafter 'the application') is a Visual Basic (6) program that can be run on Windows 98, 2000, and XP operating systems. It should be installed on a PC with a Pentium III or better microprocessor and at least 230 Mbytes of available hard disk space. Monitor screen resolution should be at least 1024 X 768 pixels but no more than 1920 X 1440 pixels. Once installed (download here), instructions for the application's use.

The application's primary daily variables (daily minimum temperature, daily maximum temperature, precipitation) were generated by modified GEM6 (Hanson, et al., 1994) weather generator code. Secondary variables (daily dew point temperature, short-wave surface radiation, net outgoing long-wave radiation, and reference grass evapotranspiration) were derived from primary variables using algorithms drawn from the FAO's 'Guidelines for Computing Crop Water Requirements' (Allen et al., 1998). Crop evapotranspiration values were then derived from the reference grass ET values using the FAO-56 single crop coefficient method.

Bibliography

Allen, R.G., Pereira, L.S., Raes, D., and Smith, M. 1998 Crop Evapotranspiration: Guidelines for Computing Crop Water Requirements. Rome, Italy: 300p.

Tools, Apps,
Models, etc.

Tools	Short Description
GeoAgro Portal	part of ICARDA Geoinformatics Unit integrated systems research portfolio. This online resource provides comprehensive information encompassing all geospatial genres in a streamlined system: remote sensing, GIS, and spatial modeling.
METIS	Intranet Database stores all ICARDA climatic data, since 1979 till 2014, also it stores data collected from many other sources like FAOCLIM, GSOD, GHEN and others, this system also provides a helpful tools in order to do search and to manage data repository.
Soil Database	Intranet Database used to store soil samples characteristics, these samples were collected from many location and later processes and analyzed in ICARDA laboratories.
AgroClimate	The application's primary daily variables (daily minimum temperature, daily maximum temperature, precipitation) were generated by modified GEM6 (Hanson, et al., 1994) weather generator code. Secondary variables (daily dew point temperature, short-wave surface radiation, net outgoing long-wave radiation, and reference grass evapotranspiration) were derived from primary variables using algorithms drawn from the FAO's 'Guidelines for Computing Crop Water Requirements' (Allen et al., 1998). Crop evapotranspiration values were then derived from the reference grass ET values using the FAO-56 single crop coefficient method.
CLIMAP & ICARDA Station Data App	Climatic data are usually provided in the form of station data, hence the information is very location-specific. However, in most cases, whether it concerns natural resource management or crop breeding, climatic information is needed for locations away, often quite far, from the climatic stations, or has to be area-specific. ICARDA Station data query and download tools
ArcCD	ArcGIS script used to do a simple downscaling process, this tool works based on Zonal Statistics and Raster Resample ArcGIS tools, and till now it's used in order to generate more than 2000 downsampled surfaces.
Arc Tools (multiline raster calc, multiclip, batch processing, etc.)	The Raster Calculator provides you a powerful tool for performing multiple tasks. You can perform mathematical calculations using operators and functions; set up selection queries, or type in Map Algebra syntax. Inputs can be raster datasets or raster layers, coverages, shapefiles, tables, constants, and numbers. This tool provides easy way to clip multi layers based on specific mask, the tool advantage is that it accepts both feature and raster layers and call the appropriate built in tool, then exports all results into one folder.
ODKs/eFeild	Custom ODK forms and kit for various field and HH, baseline surveys based on the Google ODK and Android tabs
ArcGIS netCDF	NetCDF is one of the most common formats for climatic data, and now all centers are distributing their data in this format, extracting surfaces from multidimensional files used to be a challenging process for GIS people, this tool came to help people in extracting time series surfaces from netCDF file.
Similarity Mapping	In order to manage the increasing amount of similarity mapping requests, Geoinformatics Portal team developed a similarity tool to automate the mapping process, this process consists of three parts: 1. Climate Similarity, 2. Soil Similarity, 3. Landform Similarity
Ag Workflows	ENVIU and IDL based automatic/semi-automatic Agriculture Workflows to map: 1. Crop Types 2. Crop Health/Condition 3. Biomass Estimation and 4. Ag suitability analysis
