

Meteorological Reports for ICARDA Experiment Stations in Syria and Lebanon

1990/91

International Center for Agricultural Research in the Dry Areas

Established in 1977, the International Center for Agricultural Research in the Dry Areas (ICARDA) is governed by an independent Board of Trustees. Based at Aleppo, Syria, it is one of 16 centers supported by the Consultative Group on International Agricultural Research (CGIAR), which is an international group of representatives of donor agencies, eminent agricultural scientists, and institutional administrators from developed and developing countries who guide and support its work.

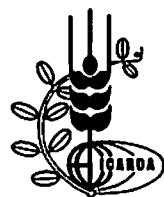

The CGIAR seeks to enhance and sustain food production and, at the same time, improve socioeconomic conditions of people, through strengthening national research systems in developing countries.

ICARDA focuses its research efforts on areas with a dry summer and where precipitation in winter ranges from 200 to 600 mm. The Center has a world responsibility for the improvement of barley, lentil, and faba bean, and a regional responsibility—in West Asia and North Africa—for the improvement of wheat, chickpea, and pasture and forage crops and the associated farming systems.

Much of ICARDA's research is carried out on a 948-hectare farm at its headquarters at Tel Hadya, about 35 km southwest of Aleppo. ICARDA also manages other sites where it tests material under a variety of agroecological conditions in Syria and Lebanon. However, the full scope of ICARDA's activities can be appreciated only when account is taken of the cooperative research carried out with many countries in West Asia and North Africa.

The results of research are transferred through ICARDA's cooperation with national and regional research institutions, with universities and ministries of agriculture, and through the technical assistance and training that the Center provides. A range of training programs are offered extending from residential courses for groups to advanced research opportunities for individuals. These efforts are supported by seminars, publications, and by specialized information services.

The Weather in Northern Syria during the 1990/91 Season

In contrast to the two previous cropping seasons, which had been dry, the 1990/91 season had a total seasonal rainfall only just below the long term average. The early part of the season was fairly dry over wide parts of northern Syria and much of the rain fell in the spring. Except during May, thermal conditions during the growing season were close to the long-term average, with fewer cold spells affecting plant growth and many fewer frost days than during the previous winter (the 35 frost days recorded at Tel Hadya represent exactly the average for the site). Because of this, because there was more moisture available to crops, and because the distribution of rainfall was such that plants could make more efficient use of it, crop yields were generally up from the low levels of the two previous years.

The first significant rains fell during the last decade of October and the first decade of November. Some more rain followed during the first decade of December. In the barley growing areas, represented by the stations of Boueidar, Ghrerife and Breda, rainfall up to the end of December was insufficient to allow emergence of barley. Germination occurred, however, so that when the rain finally returned during the first week of January, the crops emerged very fast indeed.

In the wheat growing areas, represented at the dry end of the range by Tel Hadya and by Jindiress at the wetter end, the picture was more complex. In the drier areas, rainfall in late October and early November provided enough moisture to enable some of the early planted wheat crops to emerge. But then followed three weeks without any rain, and December rainfall was sparse. As a result, these early crops suffered from severe moisture stress which reduced their yield potential unless they were irrigated. As in the barley area, at Tel Hadya plentiful rainfall started only at the beginning of January.

In the wetter wheat growing areas, however, rainfall was heavy during the third decade of October (at Jindiress 48.5 mm fell on 24 October) and sufficient to sustain growth during November and December. The growing season at Jindiress started, therefore, ten weeks before it started at the other sites. At Tel Hadya, these ten weeks growing period length could be gained through supplemental irrigation, turning the "false start" into a real one.

While January rainfall was ample, the February total stayed below the long-term average, especially in the barley growing areas. There was, however, enough moisture left in the soil to prevent undue stress to crops. From March to May, the rainfall was above average, although the May rainfall was of little benefit to crops. The soil profile started to dry out from the second decade of April onwards.

While the season so far had been neither unduly warm nor cool, May was exceptionally cold. It was the coldest May recorded at Jindiress since the ICARDA station was set up there. Even more remarkable, the -0.1°C measured at Boueidar on 10 May constitutes the first sub-zero temperature ever observed at an ICARDA station in Syria in May. Another unusual event was the hailstorm on 21 May at Tel Hadya, which caused very serious damage to those cereal crops which had not yet been harvested.

TEL HADYA
(SYRIA)

1990-1991 Season

Latitude	Longitude	Elevation
36°01'N	36°56'E	284 m

NOTE:

- 1- In addition to the standard class A pan ("Evap. Pan A"), evaporation is measured with two other pans of the same dimensions at Tel Hadya. These are covered with a loose mesh to prevent interference from birds and other animals. One of the so protected pans is raised above the ground like the original class A pan ("Evap. Pan A (Mesh)"). Observations from this pan were reported as pan evaporation in previous reports in this series. The second mesh-protected pan is sunk into the ground so that the water surface is level with the ground surface ("Evap. A-size Sunk+M"). Further evaporation measurements are taken at Tel Hadya with a GGI-3000 pan, Wild evaporation scales and a Piche evaporimeter. All these instruments are located at the main meteorological station ("1" on the plan below). The evaporation pans at all other sites are standard class A pans.
- 2- Precipitation at Tel Hadya is measured at a number of points in addition to the main meteorological station. The positions of these precipitation stations and that of the main meteorological station are shown on the plan below. At the main meteorological station, rain is measured with a standard raingauge at one meter above the ground and with a GGI-3000 raingauge at ground level. Rainfall at the other locations is measured with plastic raingauges (102 mm diameter) at one meter above the ground.

As indicated in the table page 69 ff.:

- 1- Rain Met. Stn.
- 2- Rain Blck. A South
- 3- Rain Blck. B
- 4- Rain Blck. C West
- 5- Rain Blck. C East
- 6- Rain Hilltop
- 7- Rain Farm Center

BOUEIDAR
(SYRIA)

1990-1991 Season

Latitude	Longitude	Elevation
35°40'N	37°10'E	270 m

In other ICARDA publications, the name of this site is frequently spelled "Bouider". For the meteorological report, we maintain the previously introduced form "Boueidar" for consistency with other volumes in this series.
