INSTITUTE OF MICROBIOLOGY AND BIOTECHNOLOGY, REPUBLIC OF MOLDOVA

FRUNZE NINA

QUALITY AND HEALTH OF ANTHROPOGENOUS TRANSFORMED BLACK SOILS

BĂLŢI - 2019
PURPOSE OF THE INVESTIGATIONS:

AGROECOLOGICAL APPRECIATION OF CHANGES IN THE FERTILITY OF ANTHROPIC CHERNOZEMS MODIFIED IN THE REPUBLIC OF MOLDOVA AND OF THE STABILITY OF THE MICROBIENIAN COMMUNITIES FOR THE COMPARATIVE ANALYSIS OF THE QUALITY AND "HEALTH" OF SOILS
1. Content of humus and the main nutrients in the rotation of cultures furajere of typical chernosem from the Field Station of the ASM "Biotron"

14. The relative size of the RB from the experimental variants compared to the RIS of the carbonate chernozem from the Field Cultures Stationary of the Agrarian University "Chetrosu" for the vegetation period of 2007, % compared to the standard soil virgin land.
15. The relative deviation of $q_{\text{CO}_2}$ in the arable soil and that of the virgin land of the carbonate chernosem from the Field Cultures Stationary of the Agrarian University “Chetrosu” during the vegetation period of 2007
16. Content to active carbon of the typical chernosem, according to the soil health "assessment" system of Kornell University, USA (Field Station of the ASM “Biotron”)

A – Crop rotation with lucerne
B – Crop rotation without lucerne
C1- experimental variants;
C2 - carbon of the standard variant.

A

B
Conclusions:

1. It has been established that the studied chernozem contains a large number of cells, but they present a stress state. Although most microbes showed reliable signs of viability, the specificity of the cell location suggests the probability of an insignificant vital activity of the edaphic microorganisms under the conditions of agriculturally transformed soils.

2. The in situ study revealed that most are adsorbed on soil particles, and about 1/3 were free cells, of which 67.19-90.34% were associated in aggregates of 2-3 free cells and only 32, 81-9.56% remained free.

3. The microbial biomass content rises to 252-1222 µg C / g in the soil poor in organic matter and 931-3866 µg C / g in the soil rich in organic matter. The microbial carbon reserves made up about 571-1145 kg C / ha in the Central Zone and 2511-6766 kg C / ha in the Northern Region. These values constitute to 0.95-2.54% of organic matter in the soils of the Central area of the republic and, respectively, 2.94 - 8.14% in the soils of the North area.

4. The structure of living matter 62.78-79.45% consists of the eukaryotic component. The metabolically active part of the microbial community in the soil of the natural ecosystem is about 1/3 of the total quantity (average 29.1%), and in arables analogues - 9.8 - 21.8%. The tendency of living matter to function both in arable soils and in the soil of natural biocenosis is negative.

5. The typical chernozeme in Moldova has a significant amino acid content (197 t- 317 mg N / kg soil, which is 8-11% of the total nitrogen of similar chernozems). However, in the anthropic soil are synthesized by 3-7% biomolecule more than the virgin soil. Therefore, it is possible that the smallest amount of amino acids in anthropogenic variants may be partially explained by their immediate use, while a larger amount in natural soil is retained and stored.

6. Nitrogen reserves representing 0.2% - 0.3%, decrease as a result of the long-term use of agricultural technologies, as does carbon. The lowest proportion is the ammonium fraction (0.20-0.5%). The proportion of nitrate fraction was relatively higher (7.3-14.3 times) in the arable variants: its values exceeded those of the natural fund 13 times. A significant part was formed by the fraction of nitrogen AA: 10.0-31.0% in relation to crude nitrogen and 0.80-2.30% in relation to humus.

7. Long-term exploitation of the soil has significantly altered soil respiration and its structure. The average values of the basal respiration are higher on average by 10-21% than the RIS and it becomes deeper, reflecting a discrepancy between the RB and RIS ratios, caused by the prolonged influence of the anthropogenic factors. This situation characterizes the condition of the microbial communities as stressful, and its amplitude (13-54%) - the degree of stress.

8. Soil health indicators have revealed that its main components - organic, mineral and living matter - have undergone significant changes, making the soil very vulnerable. The saturation of chernozem studied with nutrients does not satisfy the proportional ratios that characterize their satisfactory combination in humus. The situation is aggravated not only by the lack or excess of nutrients, but also by the fact that the phenomenon itself can make these and many other macro and microelements inaccessible. Therefore, the "health" of Moldovan chernozems transformed anthropically requires not only a careful attitude from the producers, but also a well thought out legislative base from the state for their protection and protection.
